What I built — and how

My agent	Wrote the Python script and the GitHub Actions workflow file
Me	Created the Telegram bot myself through @BotFather and named it
Me	Added the bot's token as a GitHub "Secret" a locked box the code can use without ever showing the value to anyone looking at it
Me	Uploaded everything to my repo with GitHub Desktop, including that workflow file
Automatic	Once that Secret was saved, GitHub Actions could unlock it each morning and run the bot on its own

- Made a list of the actual job titles I'm looking for, so the bot knows what counts as a match
- I first wanted to pull data straight from LinkedIn and Indeed, but my agent told me that breaks their rules and could get my account suspended — so we found another way
- Connects to 7 companies directly, through the same job-posting systems they already use: Greenhouse, Workable, SmartRecruiters, Workday
- Keeps track of postings I've already seen, so I never get a duplicate alert
- Connected it to GitHub Actions, so GitHub runs the bot and talks to Telegram directly — automatically, every morning, for free
- One of my files looked uploaded to GitHub but hadn't actually saved — I caught it, fixed it, and tested everything end to end. It worked, and sent me a real alert
